Frequently Asked Technical Questions

Definition

Liquid filtration is the removal of solids from liquids by flowing the contaminated liquid through a filter media that will retain the solids and allow only clean product to pass through.

Filtration Function

Using a surface filter medium to remove a volume of solids from a liquid requires that the medium should contain uniform pores smaller than the smallest particle to be removed. It should also be strong enough and possess sufficient area to hold the required volume of solids.

If a depth-type medium is used, the medium must contain an infinite number of small, irregular, continuous passages which give the solids a tortuous path to travel through. A depth medium of proper density will stop essentially all solids above a specified size.

The medium selected must withstand the manufacturer's required maximum allowable pressure drop and provide a margin of safety to cover both inadequate maintenance and line pressure surges commonly found in systems as a result of stops and starts. Facet uses both types of media in its product range.

General Applications

- Removing solids that may damage the aesthetic appearance of a product. Example: Solids in paint, bleach, liquid soaps, vinegar, plastic resin for use in plastic extrusion products.
- Removing solids which could affect chemical reaction of a product. Example: Catalyst fine in a refining process.
- Removing solids that could damage operating equipment. Example: Abrasive contaminant in hydraulic and lubricating oils.
- Removing solids that could affect a finished production item. Example: Contaminant in grinding and cutting oil of production equipment.
- Removing solids that could in some way affect the health of operating personnel. Example: Radioactive waste in primary coolant system on boiling water reactors and clean-up water in water reactor system.

Proper Selection Of Filters

Selection of media and vessel design determine the filter flow rate, dirt holding capacity, particle-size removal in one pass, overall cost of operation and initial investment.

Replaceable cartridge-type filters have wide usage and can be used in most any application. The two most important factors to consider when determining whether to use a replaceable cartridge type filters are the concentration of the solids to be retained by the filter and the required degree of filtration.

Cost Of Filtration

One realistic method of determining the "true cost" of filtration is the cost per pound of solids removed from a liquid. The four factors that make up this "true cost" are:

1. Cost of media (cartridges)
2. Cost of service parts (gaskets, etc.)
3. Cost of maintenance labor
4. Cost of downtime to service or maintain (value of lost production)

By totaling these four factors, determine a unit base as cost per pound, per gallon, per barrel, per year, etc. Although the cost of new equipment may vary, the "true cost" to the user is based on a cost per pound of solids removed. However, the achievement of a specific standard of quality cannot be measured by cost alone and this is the true value of a filter.

Capabilities

Today, more than ever, quality-conscious customers expect, and efficient plant operations dictate, the removal of solid contaminants from liquid products or processes. Filtration of particles too small for the eye to detect is essential to protect and improve quality, assure customer acceptance, prevent malfunctioning of equipment and reduce wear on machinery.

Facet filtration equipment has been designed for easy maintenance. The many easy service features reduce downtime and labor cost in maintaining equipment. These costs are important in evaluating both initial and future operational expenses.

With more than 75 years of constant research, product development and quality controlled production, Facet offers you maximum dependability, quality, innovative engineering and service.

M Series High Efficiency Pleated Paper Filter Cartridges

Facet M Series high efficiency pleated paper filter cartridges are designed to effectively remove solid contaminants such as rust, dirt, scale, granular and other types of solids. These cartridges known as the MP Series high efficiency filter cartridges are constructed to meet the demanding requirements of the industrial filter market.

Media with high efficiencies throughout the life of the cartridges are available in ratings of 0.5 to 75 microns. The filtration of potable liquids is not recommended with this series of filter cartridges.

Facet also offers a MPM Series multimedia, pleated extended area, depth filter cartridge for removing colloidal, slimy, or sludge type solids, as well as extremely fine solids, from process streams. They are available in 0.5, 1, and 2 micron ratings. The combination of multimedia pleated paper fiberglass sheets provides a unique depth filter with a large surface area.

Our pleated paper filter media is made from a variety of natural and synthetic fibers. The fibers are bonded using various resins to provide excellent filtration and solids holding characteristics.

Benefits

- Higher efficiency and longer service life = lower operating costs
- High efficiency cartridge provides superior solids holding capacity
- New spirally wound core reduces cartridge weight resulting in lower freight costs
- All metal components are epoxy powder coated to protect against corrosion
- Gaskets are Buna-N -other materials available upon request
- Available in both self-centering rod mount and screw base
- Available in numerous micron ratings: 0.5, 1, 2, 5, 10, 15, 25, 40, and 75
- Flow direction: Outside to In
- Design collapse pressure: 75 psid (5.17 bar)
- Initial differential pressure: 2 psi (0.14 bar) or less

Applications

- Fuels
- Rolling Oils
- Insulating Oils
- Paints
- Liquid Plastics
- Waxes
- Lube Oils
- Coolants
- Varnishes
- Base Oils
- Solvents (Stoddard Based)
- Petroleum Based and Synthetic Hydraulic Fluids

1818	400	0.2	2.0	0.4	2.0
2273	500	0.2	2.0	0.3	2.0

Flow rates are expressed in US Gallons per Minute (GPM).
GPM x 3.785 = Liters per Minute (LPM)

Differential pressure is listed in Pound per Square Inch (PSI).
PSI x .07 = Kilograms per Centimeter Squared (kg/cm²).

CIF Series High Efficiency Pleated Paper Coreless Filter Cartridges

The patented Facet CIF Series high efficiency coreless pleated paper filter cartridges are designed to effectively remove solid contaminants. The filtration of potable liquids is not recommended with this series of filter cartridges.

These cartridges are constructed to meet the demanding requirements of the industrial filter market. Media with high efficiency throughout the life of the cartridge is available in ratings of 0.5 to 25 microns. We recommend replacing cartridges when the differential pressure reaches 15 psi. Effective life above 15 psid is minimal.

To use the CIF Series cartridge requires the one time installation of either a single, double, triple, or quadruple length center tube kit:

- CIF1KIT
- CIF2KIT
- CIF3KIT
- CIF4KIT

Each kit contains all necessary hardware and components required to convert any housing fitted for 6" (152 mm) OD x 3½" (89 mm) ID cartridges.

Benefits

- Crushable-can reduce your disposal volume by approximately 80%
- No metal components
- Flow rates same as "M" Series
- Incinerable-check your local regulations
- Cartridge alignment is executed at top of center tube-easier, quicker
- Lightweight-contributes to reducing change out time
- Same performance and efficiency as M Series high efficiency pleated paper filter cartridges
- Nominal micron: 0.5, 1, 2, 5, 10, 15, 25
- Gaskets are Buna-N -other materials available upon request

Applications

- Gasoline
- Diesel
- Coolants
- Jet Fuel
- Kerosene
- AV-gas
- Rolling Oils
- Lube Oils
- Chemicals and Solvents

CIF Series Center Tube Kit

INSTALLATION INSTRUCTIONS

Existing Cartridge Adaptor
Center Rod and Hex Nut

Installation Instructions

To install the CIF Center Tube:

- 1- Remove existing filter cartridge. NOTE: Leave center rod in position.
- 2- Identify bottom of center tube. Only the top of center tube will accept top adaptor (3).
- 3- Place center tube assembly with the bottom guide (5) down making sure it is properly aligned on the existing cartridge adaptor.
- 4- For kit numbers CIF2, CIF3 and CIF4, be sure to properly align centering guide (4) over center rod.
- 5- Slide top adaptor (3) over center rod and secure in center tube using jam nut (6) (thinner of two nuts). Tighten to 5 foot pounds (6.78 Nm).

To install the CIF Cartridge:

- 1- Slide cartridge over center tube. Install NEW black yoke (7) domed head up.
- 2- Place rubber gasket washer (9) (supplied with filter cartridge) over center rod.
- 3- Place steel washer (10) over rubber gasket washer.
- 4- Place steel lock washer (11) over flat steel washer and secure to 5 foot pounds (6.78 Nm) with hex nut (1).

FI Series Filter Cartridges

Facet FI Series filter cartridges provide efficient and economical filtration of fluids in a wide range of applications. These industrial filter cartridges are used for removal of particulate from a broad range of products where nominal filtration is required.

Facet FI Series filter cartridges provide a large surface area for maximum dirt holding capacity, high flow rates and low initial pressure drops. The normal flow direction is outside to inside, however, specially designed cartridges are available for reverse flow.

FI Series cartridges are manufactured using pleated, resin impregnated cellulose or glass cellulose blended medias that are heat cured for strength and durability. Electro-tin plated center cores and outer bodies are the standard metal components. Cartridges are also available without the outer body. Thermosetting PVC adhesives and Buna-N gaskets are standard.

Benefits

- Resin impregnated medias provide strength and durability in demanding applications.
- Extended surface area for maximum dirt holding capacity and long life.
- One piece construction reduces downtime, cartridges change-out costs and eliminates filter bypass concerns.
- Retention ratings available from 0.5 to 100 microns.
- 90-95% nominal efficiency ratings are standard. Higher efficiency cartridges are available.
- Electro-tin plated components help prevent rust and corrosion.

Applications

- Automotive Manufacturing
- Chemicals, Resins, and Solvents
- EDM Machining
- Foundries
- Heating Oils
- Hydraulic Oils
- Hydrocarbons
- Lube Oils
- Petroleum Refining
- Pipelines and Petroleum Terminals
- Power Generation
- Pulp and Paper Industry

FI3739 Series Filter Cartridges

Facet FI3739 Series filter cartridges provide high efficiency and economical filtration of fluids in a wide variety of applications. These applications include petrochemical, oil and gas, and other related industries.

Facet FI3739 Series filter cartridges are available in several basic types of medias:

- Glass Cellulose
- Cellulose
- Polyester blend

These filter cartridges are 3.75" OD by 2.20" ID and are 38.56" nominal length. They are offered in various micron grades and ratings, which provide absolute micron ratings with Beta >200 at the stated micron rating.

Facet FI3739 Series filter cartridges are manufactured with pleated media, metal end caps with an internal O-ring seal, metal center tube, and a nylon outer sleeve for pleat stability.

This construction allows the cartridge to withstand a differential pressure of 100 psid and temperatures of 275 °F. The pleated design offers a large effective surface area from 45-60 square feet, depending on the media and micron size used.

Benefits

- Lifting handle for easy cartridge removal
- Tin plated metal end caps
- Tin plated metal, spiral, perforated center tube
- O-ring seal with a variety of elastomers available
- Nylon mesh outer sleeve
- Pleated medias for high surface area and dirt holding capacity

FIS Series Filter Cartridges

Facet FIS Series filter cartridges provide efficient filtration of fluids in a wide variety of applications, particularly in water based fluids. This range of reliable filter cartridges is used to remove particulate from a broad range of process streams including water based fluids, chemicals and petroleum based fluids. The high performance filter media used in FIS Series filter cartridges will not soften or pre-maturely plug in water based fluids unlike filter cartridges that use cellulose based filter media.

FIS Series filter cartridges are manufactured using proprietary combinations of polyester and micro-fiberglass filter media to achieve the desired removal rating. The pleated filter media in the FIS Series cartridge is supported by epoxy coated wire to ensure mechanical stability. The use of synthetic and non-woven filter media results in significantly higher dirt holding capacity than similar cartridges that rely solely on cellulose filter media. As a result of their innovative design, FIS Series cartridges deliver higher flow rates at lower initial pressure drops and longer on-stream life cycles when compared to conventional cellulose filter cartridges of equal efficiency.

Electro-tin plated, spiral center cores and electroplated end caps are standard components. Special configurations are available with a rigid outer cage for increased mechanical strength.

Benefits

- Synthetic medias provide high efficiencies, superior strength and durability
- Superior performance in water based fluids, resulting in longer life
- Extended surface area for maximum dirt holding capacity and long life
- One piece construction reduces downtime, cartridge change-out costs and eliminates filter bypass concerns
- Retention ratings available from 0.5 to 40 microns
- Electro-tin plated components help prevent rust and corrosion
- A variety of adhesives and gasket materials offer a wide range of compatibility

Applications

- Amines
- Chemicals, Resins, and Solvents
- Coolants
- Cooling and Process Water
- Glycols and Glycol Solutions
- Hydraulic Oils
- Lube Oils and Seal Oils
- Oil and Water Filtration
- Petroleum Refining Applications
- Power Generation
- Pulp and Paper Industry

MM Series Screen Wrapped Filter Cartridges

Benefits

- Cleanable and reusable
- High operating temperatures
- Wide range of pH compatibility
- All stainless steel components
- Flow direction: Outside to In

Applications

- Resins
- Waxes
- High Viscosity Fluids
- Caustic Applications

Facet MM Series screen wrapped cartridges are cleanable and reusable stainless steel surface filters for removing solids from liquids, compressed air, and most gaseous fluids.

MM Series screen cartridges are assembled by wrapping layers of stainless steel mesh cloth around a perforated outer support shell. These cartridges are available in micron ratings from 5 to 750. They provide approximately 255 sq. in. (1645 sq. cm.) of effective filtration area. Recommended flow rate is based on specific application.

M Series Filter Housings

M Series filter housings use any of Facet's M Series high efficiency filter cartridges. A single pass of product through the system removes solids such as rust, dirt, scale, granules and other particles commonly found in liquid process streams.

M Series filter housings are available in vertical or horizontal configuration in several standard and custom sizes to accommodate specific flow and filtration requirements. They are designed with no internal moving parts to provide easy service and reduced maintenance costs. Each housing is manufactured using quality materials and workmanship to give long-lasting, dependable service.

M Series filter housings can be fitted with either multiple single-length cartridges, stacked 1, 2 or 3 high, or their double-length or triple-length equivalents.

Standard Design Features

- Body: Welded carbon steel construction — other materials available on request
- ASME Code, Section VIII, Div. 1 construction
- Designed for 150 psi @ 250°F (10.3 bar @ 121 °C) — higher pressure and temperature ratings available on request
- Head closures:
Style 1, thru-bolt; Styles 2 and 3, swing bolt
- Head gasket: Buna-N o-ring —other materials available on request
- Inlet and outlet permanently marked
- Exterior: Multipurpose prime coated
- Head lift furnished on 20" (508 mm) and larger

Standard Connections

- Inlet and outlet:
Style 1, 3000# NPT; Styles 2 and 3, 150# RF (ANSI) flanged
- Side and bottom drain: 3000# NPT
- Vent and relief valve: 3/4" 3000# NPT
- Pressure gauge: 1/4" 3000# NPT

Options

- Air Eliminator
- Differential pressure gauge
- Pressure relief valve
- Manual drain valve
- Interior epoxy coating

**SMALLER HOUSINGS AVAILABLE.

Liquid / Liquid Separation General Description

Development of new media and treatment of existing media permit use of these coalescers for essentially all process streams where entrainment of solids and liquid contaminants are present.

Figure 1. A typical two-stage vertical coalescer

Three basic designs of cartridge-type coalescers are available for application in chemical processing. They are comprised of single-stage, two-stage, and three-stage units wherein one, two or three types of cartridges are provided. The configuration of each design will vary with the process application and efficiency requirements.

In determining the design of coalescer to be used, the maximum operating conditions and minimum performance efficiencies must be established. With the performance requirements established, the determination of the basic design and media to be utilized is made. Among the various factors which must be considered in arriving at the correct design are the physical characteristics of the fluid to be processed. This applies not only to the continuous phase but equally well to the discontinuous phase. Since all coalescers, whether one-, two-, or three-stage rely to a greater or lesser degree on the natural forces of gravity, the difference in the specific gravity of the two liquids is important. As will be discussed later, the discontinuous phase may be lighter or heavier than the continuous phase without affecting the efficiency of the unit, provided sufficient differential in gravity exists. Since the natural forces of gravity enter into the operation of the equipment, the viscosity of the fluids being processed must also be taken into consideration.

One of the most important single factors to consider in the design of cartridge type coalescers is the interfacial tension between the continuous and discontinuous phase. Since the interfacial tension controls the maximum droplet size of the discontinuous phase and relative wetting of separating surface, the selection of a coalescing media is of prime importance when low interfacial tension values are to be encountered.

Since most fluid process streams contain solids contamination of one form or another, consideration must be given to the type of contaminant involved and the amount of contaminant in the fluid. The next factor that affects the ultimate design is the particle size distribution. From the particle size distribution curve, a determination of how much of the solids contaminant to be retained in the cartridges can be made. The fact that the solids to be filtered are either hydrophobic or hydrophilic is of importance. If a solid is hydrophobic it will be borne through the system by the hydrocarbon phase and will be more difficult to filter. The hydrophilic solid is carried by the discontinuous water phase and during the mechanical action of coalescence, this solid will largely be deposited on the media of coalescer cartridge.

Coalescer Cartridge

The coalescer cartridge is made up of one or more layers of media. This media is primarily a porous membrane which retains its dimensional stability by the use of thermal setting resins or binders. Careful selection of the media is imperative to insure that the fluid stream being processed does not remove the binder in the media, which would result in media collapse and contamination of the fluid. In order to assure that coalescing of the discontinuous phase is complete, the media must possess an infinite number of irregular continuous passages of very small diameter. These passages are such that by impingement and preferential wetting of the media surface, the discontinuous phase is commingled to a sufficient size where it can be removed from the continuous phase by gravitational force or by contacting a second stage, commonly referred to as a separator cartridge.

Because of the extremely small pore size of the irregular continuous passages of the coalescing media an accessory function of the media becomes one of removing solids particles. Therefore, if a given coalescing media possesses a sufficiently fine pore size to affect coalescing of a finely dispersed discontinuous phase, it will, at the same time, provide excellent filtration

Liquid / Liquid Separation General Description

characteristics. The degree of filtration will be in direct relation to the size of the openings and the total solids retention will vary with the type and depth of media used.

One of the most important single factors regarding the application of cartridge-type coalescers to fluid process streams is the interfacial tension between the continuous and discontinuous phase. Below values of 20 dyne/cm, the size of the particles in the dispersed phase becomes progressively smaller and coalescing becomes more difficult. Media is available which will coalesce at values of less than 10 dyne/cm; however, additional consideration must be made for these reduced values. Under these conditions, the media of the coalescer cartridge must have even smaller diameter pores to insure that all of the dispersed phase contacts one or more surfaces during its passage through the media. Preferential wetting of the media by the dispersed phase will facilitate complete coalescing.

Coalescing media is provided in many forms, the most common being multiple layers of media formed into cylindrical cartridges ranging in size from 4 to 6 inches in diameter and 10 to 57 inches in length. The direction of flow can be either outside-to-inside or inside-to-outside. The most common flow pattern in cartridge type coalescers is inside-to-outside. Higher flow rates can be obtained in the inside-to-outside cartridge coalescer due to the fact that the linear velocity of the fluid passing through the media is progressively reduced as the fluid approaches the outer extremities of the cartridge. This condition permits the discontinuous phase to be commingled into a larger droplet size with the result that the load on the second stage is greatly reduced.

Other forms of coalescing media in bulk form are available and are widely used in some applications. Among the more common types of bulk coalescing media are bonded and unbonded glass fibers, metallic wool of various types, and treated wood fibers. Bulk type coalescing media of the types mentioned herein are normally used in single-stage coalescers. The density of the bulk coalescing media will vary with the type of media used in the installation. Typical bulk densities of this type media will range from 1½ to 4 pounds/cubic foot for glass fibers and up to 20 pounds/cubic foot for metal wool.

The degree of coalescing and the nominal pore size of the bulk cartridge can be relatively controlled by the density of the material. Unbonded glass fibers lend

themselves to applications wherein the solvent action of the continuous or discontinuous phase prohibits use of bonded materials. Metallic fiber can be used to a great advantage in applications where the pH of the fluid being processed exceeds the limits of glass fibers or other forms of conventional coalescing media. Other forms of coalescing media are also available such as polyethylene encapsulated fibers, inorganic fibers and sintered materials.

Figure 2. A typical single-stage coalescer

Separator Cartridge

The separator cartridge is made up of a single media. This media must allow free passage of the continuous phase and can be treated to repel the discontinuous phase. The separator cartridge is normally comprised of one type or layer of media. The type of media will vary with the application. The separator media must permit maximum flow of the continuous phase at minimum pressure differential. This media must be superficially treated or possess inherent characteristics which will permit free passage of the continuous phase while repelling the discontinuous phase. A common media for this application is silicone-treated cellulose fibers.

The media must be dimensionally stable in the presence of the fluids being processed since any swelling of the fibers due to absorption will result in a change in the pore size of the media. Effectiveness of the separator cartridge is entirely dependent upon the repellent characteristics of the media to the discontinuous phase and the critical pressure at which the discontinuous phase will be forced through the pores of the media. It is, therefore, of absolute necessity that the pore size of the media remain unchanged; otherwise, the critical pressure differential

Liquid / Liquid Separation General Description

will be exceeded and the cartridge will fail to repel the discontinuous phase. Critical rupture pressure can be expressed by the following formula:

$$p = 2\gamma/r$$

where p is the differential pressure (in. Hg), γ is the interfacial tension (dyne/cm), and r is the radius of maximum pore (micron).

Other materials are available for use as a separator media. One of the more common materials is the use of polytetrafluoroethylene coating on fine-mesh wire filter cloth. This particular type of separator cartridge lends itself to those applications where the continuous phase would wash out or otherwise be detrimental to the silicone-impregnated cellulose materials. An auxiliary function of the separator cartridge is one of filtration. Since the pore size of the separator media is controlled, this media then becomes a secondary filter to prevent migration of fibers from the preceding stages; or in the event of mechanical failure of the coalescer cartridge, the separator cartridge will prevent solids contaminant from flowing into the effluent stream.

Filter Cartridge

In three-stage units the first stage is made up of single or multiple installations of one of the various types of filter cartridges. The function of this cartridge is one of removing solids contaminants only. Its purpose is to reduce the loading on the second-stage coalescer cartridge, thereby greatly improving coalescer life and to insure ultimate efficiency from the media. The direction of flow through the filter cartridge is from outside-to-inside. This design permits maximum solids retention in a minimum envelope size.

The selection of media for the filter cartridge will be determined by a number of factors; the most important of which are chemical characteristics of fluid to be processed, temperature, amount of solids contaminants in the process stream, particle size distribution, maximum particle size permitted in effluent, and minimum solids retention before change is required. The cartridge may be made from any of the various common media such as pleated cellulose, woven materials, and impregnated organic fibers. For those applications where the process stream prevents use of bonded or impregnated media due to solvent action, other materials are used. There are now available polyethylene-encapsulated fibers which retain all filtration

characteristics of impregnated cellulose with regard to pore size and offer essentially zero media migration. This material now affords economical filtration to numerous process applications which are beyond the operational limits of low cost media.

Two-Stage Unit

A typical two-stage vertical coalescer is shown in Figure 1. This design is commonly referred to as a filter separator.

The contaminated fluid enters the lower inlet chamber and flows upward into the inside of the multiple coalescer cartridges. In this area of reduced velocity, the initial phase of commingling is begun. When the fluid contacts the initial surface of the media, any large particles of contaminant will be filtered from the stream. As the fluid continues its tortuous passage through the media, the discontinuous phase is impinged upon the infinite surfaces and commingling of the dispersed particles results. As the two liquid phases near the outer surface of the coalescer cartridge, the discontinuous phase has been coalesced to large droplets. Simultaneously with coalescing of the discontinuous phase the media is filtering solids contaminant from the process stream.

As the two liquid phases flow from the outside surface of the coalescer cartridge, the large droplets of the discontinuous phase will fall by gravitational force to the sump or collection area. The lower velocity in this area greatly reduces the possibility of rupture of the coalesced droplets of the dispersed phase. Any remaining entrainment of the discontinuous phase will be repelled by the separator cartridge. In addition to preventing any passage of the discontinuous phase into the effluent stream this cartridge also performs as a secondary filter in event of mechanical failure or bypass of the coalescer cartridge.

The two-stage unit is also provided in horizontal configurations. In this design the sump for accumulation of the discontinuous phase may be located below or on top of the horizontal vessel. Normally the coalescer cartridges are installed in one end of the vessel and the separator cartridges in the opposite end. The void area between the ends of the cartridges provide fall-out area for the discontinuous phase. This type of two-stage design is particularly desirable where the viscosity of the fluids being processed is relatively high or where the differential gravity between the two products is relatively low. This design further lends itself to application on streams where

Liquid / Liquid Separation General Description

the discontinuous phase is lighter than the continuous phase with the result that the accumulation sump must be installed on the top of the vessel.

Another design of the two-stage unit follows the general configuration of the vertical design wherein the unit is rotated 90 degrees on its normal axis and installed in a horizontal position. The coalescer cartridges are installed in the lower section of the horizontal shell and the separator cartridges are installed in the upper or top section of the horizontal vessel. A vertical accumulator sump for collection of the discontinuous phase is added to the horizontal chamber.

Two-Stage Unit Application

Typical of a two-stage coalescer installation is the following:

Process problem: Removal of undissolved water containing hydrochloric acid from perchloroethylene.

Operating conditions:

Required performance: Nominal size of effluent solid

	Heavy Phase	Light Phase
Feed Rate lb./hr.	112,000	10,000
Specific gravity	1.6	1.0
Liquid	Perchloroethylene	Water
pH		5.0
Temperature, °F		122
Pressure, lb./sq. in. gauge		150

particle five microns. Effluent stream to contain not more than 5 ppm undissolved water.

For this installation a horizontal two-stage unit using multiple coalescer and separator cartridges was used. This design was selected primarily because the discontinuous water phase is lighter than the continuous phase. A second important factor in selection of this design was the high concentration of water in the process stream. The settling area between the two stages permits the major portion of the water to rise to the accumulator sump before reaching the separator cartridges.

The physical and chemical characteristics of the continuous phase permitted use of conventional coalescing and separating media. The hydrochloric acid dissolved in the water phase had reduced the pH to five which is within normal operating limits of glass fibers used

in the coalescer cartridges and silicone treated cellulose in the separator cartridges. The operating temperature was considerably less than the 275°F permitted for this type of media.

All metal in contact with the process fluid was of stainless steel and all non-metallic parts are resistant to the corrosive action of the hydrochloric acid solution.

Single-Stage Unit

A typical single-stage coalescer is shown in Figure 2. Single-stage units may be comprised of multiple installation of coalescer cartridges as illustrated, or the entire cross section of the vessel may be packed with a bulk-type media. This design is used when the differential in specific gravity of the two liquid phases is sufficient to provide separation by gravitational force or where a separator cartridge would not possess sufficient repellent characteristics to the discontinuous phase.

In the design of single-stage units, the size of the vessel is of prime consideration since separation is entirely dependent upon the difference in the density of the two liquids. Linear velocity in the settling area of the vessel will vary from 0.25 ft/sec on light fluids to 0.10 ft/sec on heavier products. If the discontinuous phase is lighter than the continuous phase the accumulator chamber is placed on top of the vessel.

The contaminated fluid flows into the large inlet chamber and the immediate reduction in velocity will permit a portion of the entrained discontinuous phase and solids to settle out. The discontinuous phase will then pass through the lower half of the coalescer pack. Any remaining entrainment is coalesced and solids are filtered from the fluid as it flows through the media.

Single-Stage Unit Application

Typical of a single-stage coalescer installation is the following:

Process problem: Removal of entrained water containing sodium hydroxide from butadiene.

Operating conditions: Specific gravity 0.628 at 60°F. Flow 200 gpm Entrained water 10% volume; pH of water 9.5 to 10.0. Solids contaminant negligible.

Required performance: Water not to exceed 50 ppm in effluent. For the above installation a single-stage horizontal unit using a bulk-type coalescer cartridge was used. The design was selected because the pH value of

Liquid / Liquid Separation General Description

the water phase exceeds the recommended values for secondary separator cartridges of conventional media. The media selected was a fine grade stainless steel wool compressed to an optimum density to provide maximum contact surface for coalescing and minimum differential pressure.

Figure 3. A typical three-stage horizontal coalescer

Three-Stage Unit

A typical three-stage horizontal coalescer is shown in Figure 3. This unit consists of coalescer and separator cartridges as used in the horizontal two-stage device, and is provided with a first-stage cartridge whose primary function is the removal of solids contaminant from the stream. The product enters the low-velocity inlet chamber where the larger particles of solids contaminant will settle out by gravitational force. In this area, any sludge or other heavy entrainment will also settle out and accumulate in an auxiliary sump. Controls may be provided on the auxiliary sump for automatic blowdown of the accumulated material. As the fluid flows through the first-stage filter cartridge, the solids contaminant is filtered from the stream. Simultaneously, some initial coalescing of the discontinuous phase may occur depending upon the media used in the filter cartridge and the characteristics of the discontinuous phase.

As the filtered product and discontinuous phase flows from the first-stage filter cartridge, it is discharged directly into the inside of the second-stage coalescer cartridge. The second-stage coalescer cartridge then performs the function of completing the coalescing of the discontinuous phase and filtering out any remaining solids which may be in the stream. Immediately downstream from the coalescer cartridge is a void area which provides settling

space for gravitational fallout of the discontinuous phase. As the product flows to the outlet through the third-stage separator cartridge any remaining entrainment of the coalesced discontinuous phase is repelled and the clean, dry product leaves the vessel.

Use of a three-stage device permits a very wide selection of filter and coalescing media. This unit offers great advantages for those installations where the solids contaminant in the process stream is relatively high, i.e., 5 mg/l. The first stage filter cartridges can be removed from the unit without disconnecting any of the piping or without removing the cartridges in the second- or third-stages.

Application

The use of cartridge-type coalescers, as applied to the chemical process industry, has resulted from the development of new media and treatment of existing media to permit their use. The art of coalescing has advanced to a point where there are only a few isolated process systems where cartridge-type coalescers cannot be utilized.

Cartridge-type coalescers can be provided for essentially all process streams where entrainment of solids and liquid contaminant is present, the only limiting factors being equal density of the two liquid phases or essentially zero interfacial tension.

Coalescer and Separator Cartridges General Description

Facet coalescer and separator cartridges are mechanical devices to filter solids and separate two immiscible liquids. The most common uses are the filtration and separation of water from aviation fuel, hydrocarbons, process streams, fuel oil, diesel, and various types of oil.

How They Function

In order to provide efficient coalescing of an aqueous discontinuous phase, the media used in the coalescer cartridge must contain an infinite number of small, continuous, irregular passages of a very small diameter. As the continuous phase passes through the media, the discontinuous phase is broken out by impingement, generally in the form of minute particles. As the particles pass through the entire depth of the media, they commingle or coalesce into discrete droplet size, capable of settling due to gravity.

Because coalescing requires a depth media with small irregular passages, it is also an excellent filter media for removing solids. A coalescer capable of producing water removal will also remove solids as low as 1 micron. If less efficient filtration is desired, the coalescing will also be less efficient.

The function of the separator cartridge in the second-stage (in a two-stage design) is to provide a hydrophobic membrane so the discontinuous phase droplets are repelled if they do not completely settle out by gravity, and to act as a secondary barrier to solids. A cylindrically wrapped separator cartridge is available in a Teflon® coated 200 mesh monel screen to provide hydrophobic separation. Screen cartridges will remove solids down to 50 microns. The pleated paper separator cartridges have been treated to repel water and are capable of removing solids down to 5 microns.

Selection Criteria

In selecting the media for the desired degree of separation, the chemical properties, operating temperature, volume of the discontinuous phase and allowable initial differential pressure must all be considered.

Further, a filter separator housing is durable and can last for many years. In making a selection, it is important to consider future needs. Undersized or marginally sized housings may not provide the user with the option to update performance by a simple change in coalescer or separator cartridge media. The slightly higher initial investment in a larger housing can be offset by future demands for increased performance.

A two-stage filter separator should be used where the highest degree of water removal is required. A typical application is the removal of water from jet fuel prior to aircraft fueling. Other typical applications include the removal of water from various process streams prior to distribution.

A single-stage filter separator is used where less efficient water and solids removal is required or where the processed fluid is not compatible with the second-stage separator cartridge. Typical applications are the removal of gross water at an intermediate process stage prior to further refinement.

Cost of Filtration Separation

Through many years of experience, it has been found that the most realistic method of determining the true cost of filtration is based on the cost per unit of product processed. There are four factors which make up the true cost of filtration separation:

1. Cost of media (cartridges, etc.)
2. Cost of service parts (gaskets, etc.)
3. Cost of maintenance labor
4. Cost of downtime to service or maintain (value of lost production)

By totaling these factors, filtration costs may be determined for various unit bases such as cost per pound, per gallon, per barrel, per year, etc. While cost of new equipment may vary, the true cost to the user is based on the cost per unit processed.

General

A variety of Facet coalescers are available, each designed to meet a specific need. These cartridges are the result of more than 75 years of researching the separation of immiscible liquids.

Experience has proven that no one individual cartridge media arrangement can meet all applications for refineries, petrochemical plants, bulk storage terminals, diesel and fuel oils, turbine fuels, and lube oils.

Facet has developed many different coalescer cartridges specifically designed to give proven performance in applications at sea, terminals, offshore drilling, power plants, refineries, petrochemical plants, truck stops, marinas and manufacturing plants.

The breadth of this experience has taught us that coalescer cartridges must have good basic engineering, dedicated production equipment and tight quality control by qualified personnel to meet demanding use. Coalescer cartridges are made to perform a specific task and most industrial applications can be handled with one of the standard or specialized categories.

Flexibility

With the exception of the EB Series single-stage coalescer, all of the coalescer cartridges may be used with companion separator cartridges or as a single-stage. (Performance efficiency, when used as a single-stage, is predicated on the specific operating conditions.) All cartridges, in comparable lengths are dimensionally interchangeable, adding greatly to housing flexibility for varied use.

Standard Categories

- **2 Micron**
CR Series cartridges are fine filters for solids retention and water removal. They have wide industrial applications including process industries, turbine lube oils, turbine fuels and bulk storage terminals.
- **5 Micron**
CB Series cartridges are for solids retention and water removal where fine filtration is not required. They are widely used in the refining and petrochemical industries.
- **25 Micron**
CC Series cartridges are medium filters for solids retention and water removal. They are designed for general industrial applications where exacting performance is not required.

Specialized Categories

- **15 Micron Caustic**
CMP Series cartridges are specialized filters for solids retention and water removal. They are designed specifically for the refining process where removal of aqueous or caustic solution is required.
- **1 to 50 Micron Emulsion Breaker**
EB Series cartridges are for solids retention and oil removal from water. They can be used in a variety of applications including marine, petroleum, transportation, power generation and industrial.
- **10 Micron Aromatic**
U5 Series cartridges are designed for solids retention and water removal from aromatics.

Description

Facet industrial coalescer cartridges provide efficient and economical filtration and coalescence of fluids in a wide range of applications where EI certification is not required. This broad range of liquid/liquid coalescers provides greater coalescing efficiency and contaminant holding capacity than most conventional coalescers or other separation techniques. As a result, Facet industrial coalescers improve product quality, reduce maintenance costs and help prevent unscheduled shutdowns.

Facet industrial coalescer cartridges are manufactured using proprietary combinations of high performance filter media. Years of research and development in phase separation technology has enabled Facet to develop a very broad range of filter grades to meet the stringent requirements of industrial applications.

Facet industrial coalescer cartridges are available in numerous configurations to replace most conventional coalescing cartridges. In addition, Facet can develop special configurations to meet specific applications requirements.

Benefits

- High Performance filter media provides effective particle removal and coalescence in a wide range of applications
- Proprietary design provides superior performance when compared to conventional coalescing cartridges
- Continuous lengths minimize process downtime, reduce cartridge change-out costs and eliminate filter bypass concerns
- Retention ratings available from 1 to 25 microns
- 90-95% nominal efficiency solids removal ratings. Water removal efficiency is by series
- Electro-tin plated components help prevent rust and corrosion. Coated components are available as standard options
- 75 psid burst strength permits use in demanding applications

Applications

- Chemicals, Resins, and Solvents
- Hydraulic Oils
- Hydrocarbons
- Petroleum Refining
- Pipelines and Petroleum Terminals
- Power Generation
- Pulp and Paper Industry
- Transformer Oils
- Turbine Oils

Oil Water Cartridges EB Series

Facet EB Series coalescer cartridges are for removing oil from water. Using a variety of media, these coalescer cartridges use the principle of mechanical impingement and preferential wetting to break any mechanical emulsion of oil and water. Using the force of gravity, the lighter liquid (oil) rises to the top of the vessel where it can be drawn off and the water flows to the bottom of the vessel and out the outlet connection.

Benefits

- pH range from 5 to 9
- Multi-layered media for solids holding
- Solids removal as specified
- Removes oil down to 5 ppm
- Balanced flow characteristics
- Self-centering rod mount and screw base type available
- Recommended maximum operating temperature: 240 °F (115 °C)
- Maximum differential pressure: 75 psi (5.17 bar)
- Flow direction: Inside to out

Applications

Marine

- Bilge & Ballast water
- Ship building and repair yards
- Commercial marine ports

Petroleum

- Stormwater from bulk storage
- Tank bottom condensate
- Refinery wastewater

Transportation

- Railroad yard maintenance and washing
- Truck loading terminals
- Airport fuel storage and maintenance

Power Generation

- Boiler feed water
- Cooling water
- Floor drains in turbine rooms
- Fuel storage stormwater runoff

Industrial

- Petrochemical plants
- Steel mills
- Manufacturing plants
- Boiler feed water

CC-U5-2DP Aromatic Coalescer Cartridges

Standard Design Features

- Solids removal: 10 micron
- Water removal down to 10 ppm
- Recommended maximum operating temperature: 300 °F (149 °C)
- pH range from 1 to 9
- Balanced cartridge flow characteristics
- Self-centering rod mount
- Maximum differential pressure: 75 psi (5.17 bar)
- Flow direction: Inside to out
- Recommended flow rate: 10 gpm (378 lpm) per 14" cartridge length

Facet CC-U5-2DP Series coalescer cartridges are designed for removing free and entrained water from BTEX compounds –xylene, benzene, toluene and ethylbenzene, or removing BTEX compounds from water. When removing water, a two-stage housing using Facet's synthetic separator cartridges as the second stage will greatly improve efficiency. When removing BTEX compounds from water, use the CC-U5-2DP in a single-stage housing.

This coalescer cartridge is constructed of a single piece fiberglass tube, stainless steel metal components and non-asbestos gaskets. It is 6" (152 mm) OD, by 3½" (89 mm) ID by 14½" (370 mm) long which makes it interchangeable with most 6" (152 mm) OD coalescer cartridges.

Note: Other lengths are available.

Industrial Separator Cartridges

Description

Facet industrial separator cartridges provide efficient separation of water in a wide range of fluid process streams. These high performance liquid/liquid separators are used in applications where EI certification is not required. The use of Facet industrial separator cartridges instead of conventional liquid/liquid separators can help reduce operating costs and improve product quality.

Facet industrial separator cartridges are manufactured using proprietary combinations of high performance filter media and pleat configurations. Facet has developed continuous length separator cartridges to retrofit most commercially available single length separators.

The use of continuous length separators minimizes process downtime, reduces cartridge change-out costs and eliminates filter bypass concerns.

Generally, the pleated paper configuration is considered the best general purpose separator having an extended surface area and being changed simultaneously with its companion coalescer. Selection must be based on the physical and chemical properties of both phases. As in the case of coalescer cartridges, separator cartridges may be used in most finished petroleum products, but caution must be exercised in compatibility of not only the media, but adhesives, metal parts and gaskets.

Pleated paper separators provide a 5 micron filtration barrier. It is also offered in a 25 micron.

Teflon separators provide a 74 micron filtration barrier.

Synthetic separators provide a 50 micron filtration barrier.

Both Teflon and synthetic separator cartridges can be cleaned and reused in accordance with Facet procedures.

Facet is continually working with customers to optimize separator performance. Facet industrial separator cartridges are available in numerous configurations to replace most conventional coalescing cartridges. Facet can develop special configurations to meet specific applications requirements.

Benefits

- Proprietary filter media provides a high performance in a wide range of applications
- Continuous lengths minimize process downtime, reduce cartridge change-out costs and eliminate filter bypass concerns
- Designed for balanced flow through cartridge
- Electro-tin plated components help prevent rust and corrosion. Coated components are available as standard options
- Synthetic, plated, or coated end caps available

Applications

- Chemicals, Resins, and Solvents
- Hydraulic Oils
- Hydrocarbons
- Petroleum Refining
- Pipelines and Petroleum Terminals
- Power Generation
- Pulp and Paper Industry
- Transformer Oils
- Turbine Oils

Single-Stage Repack Coalescers

Single-stage separation by use of packed mass media is generally used for hydrocarbons of lighter specific gravities and process streams where the removal of water and solids is of vital importance.

Separation is first started when the liquid enters the vessel. Due to the substantially reduced velocity, free water starts to fall out by gravity. As it progresses through the mass packed media, further separation occurs by impingement of the water droplets on the media. At the same time, solids tend to fall out as the liquid enters the vessel at reduced velocity but are further removed by filtration as the flow continues through the mass media.

Settling zones permit a natural separation of water due to the difference in the specific gravities of the two phases.

Mass packed coalescing media are available in various styles and materials. Selection is based on the condition of the liquid as to temperature, acidity and specific gravity. A second criterion is the efficiency of water and solids removal desired. Heavy solids or certain types of solids will tend to either blind off the surface of the media and/or compress them to the point that they will no longer function as a coalescer.

In the event solids are expected to be moderate to heavy (in excess of 5 ppm), consideration should be given to using the wafer type. This type permits change out of the first or second upstream wafers, which may contain a heavy load of solids, while the third and successive downstream wafers are relatively free of solids and still effective coalescers.

The outside diameter of all repacks is sized to the inside diameter of the vessel. Thus, each repack is personalized to the vessel. Further, densities will vary depending upon the media used.

Cylindrical Repacks

This cylindrically packed cartridge is for use as a coalescer medium for light hydrocarbons or as strainers on most petroleum products. They are available in selected Aspen wood excelsior, glass fibers, carbon steel or Type 430 steel wool.

Wafer Repacks

The wafer packed cartridge is for use as a coalescer or as a strainer where heavy solids loads are expected or where solids tend to blind off the face without affecting the remaining 75% - 80% of the cartridge. They are available in selected Aspen wood excelsior, glass fibers, carbon steel or Type 430 steel wool.

Combination Repacks

Combination repacks are for use in process streams where the following conditions may be found; sulfuric acid concentrations as high as 80% - 90%, aqueous solutions with pH from 1 to 9 and temperatures up to 350 °F (176 °C). They are available with alternate layers of glass fiber bat material and Type 430 metal mesh spacers to prevent excessive compression due to high solids loads.

Two-Stage Vertical Coalescer Separator Housings

VCS Series

Facet VCS Series two-stage vertical coalescer separator housings are mechanical devices designed to filter solids and separate two immiscible liquids. Using Facet's first-stage coalescer cartridges and second stage separator cartridges, they provide the highest degree of water and solids removal available.

These quality Facet products are designed for installations in petrochemical plants, refineries, power plants, bulk storage terminals, offshore platforms, manufacturing plants and many other industrial applications.

Standard Housing Designs

- Body: Welded carbon steel construction — other materials available by request
- ASME Code, Section VIII, Div. 1, stamped and certified
- Designed for 150 psi @ 250 °F (10.34 bar @ 121 °C) — higher pressures and temperatures available by request
- Inlet and outlet permanently marked
- Exterior: Prime coated
- Swing bolt head closures
- Head Gasket: Buna-N o-ring —other materials available by request
- Head lift furnished on 18" (457 mm) OD and larger

Standard Connections

- Inlet and outlet: 150# RF (ANSI) flanged
- All other connections are 3000# NPT couplings

Options

- Automatic air eliminator
- Differential pressure gauge
- Immersion heaters
- Liquid level gauge
- Pressure relief valve
- Sampling probe
- Special connections available
- Drain valves
- Blind cover for pilot control mounting flange
- Interior epoxy coating

NOTE: The above flow rates are sizing guides only. Calculations of specific service conditions may result in units with flow rates other than those shown above.

OA = On Application

(1) Nominal Micron rating is based on removing 96 to 98% of all solids larger than the rating shown in one pass through a clean cartridge.

(2) Flow rates are based on normal conditions when the interfacial tension between the water and the continuous phase is not less than 36 dynes per centimeter, operating temperature does not exceed 240°F, and pH value between 5 and 9.

Single-Stage Coalescer Housings

HP Series

Facet HP Series single-stage coalescers use wafer repacks to remove gross amounts of water and solids from hydrocarbons. They are available in several standard sizes to accommodate flows from 10 to 2000 gpm (38 to 7570 lpm). They provide protection to filtration systems from gross amounts of water and solids that are commonly carried through inbound transport pipelines.

HP Series housings offer an option of using coalescer cartridges for more efficient solids separation and liquid-liquid water separation. Use of an adaptor kit permits returning to the use of repacks at any time.

HP Series housings have no internal moving parts and are designed for easy servicing, thereby reducing maintenance costs. Each housing is manufactured with quality workmanship and materials to give long-lasting and dependable service.

Variations from standard design are available in higher pressures, other materials, special connections or other quick opening closures.

Standard Design Features

- Body: Carbon steel construction
- ASME Code, Section VIII, Div. 1, stamped and certified
- Designed for 150 psi @ 250 °F (10.34 bar @ 121 °C)
- Housing Closure:
 - Blind cover on housings less than 14" (356 mm) OD
 - Swing bolt closure on housings 14" (356 mm) OD and larger
- Housing Covers:
 - Removable on housing up to 14" (356 mm) OD
 - Hinged on housings 14" (356 mm) thru 36" (914 mm) OD
 - Rotating davits on housings 42" (1067 mm) OD and larger
- Head Gasket: Buna-N — other material available by request
- Exterior: Prime coated
- Saddle supports for pier mounting

Options

- Steel stands available
- Internal epoxy coating

Standard Connections

- Inlet and outlet: 150# RF (ANSI) flanged
- All other connections are 3000# NPT female type couplings

Conversion Kits

CKS Series

Facet CKS Series conversion kits are designed to upgrade HP Series separators which presently use excelsior repacks in order to provide more efficient solids filtration and water separation.

They are designed for retrofit in vessels without need for alteration to basic vessel design in order to permit use of current design first stage coalescer cartridges which flow inside-out. Use of various Facet cartridges will permit various efficiencies desired by the user. Conversions enable use of out-of-service equipment which would otherwise be in storage or disposed of by sale or scrap. Kits installed without vessel modifications permit return to use of excelsior cartridges when desired.

CKS Series conversion kits permit the use of any of the Facet CA, CR, CB, CC, CMP, AG or U5 Series cartridges, all 6" (152 mm) OD, rigid, high flow cartridges. All cartridges are capable of withstanding differential pressure of 75 psi (5.17 bar) without structural failure.

Standard Design Features

- Kits contain all necessary parts for conversion including hardware, cartridges and gaskets.

Materials

- Cartridge holding plates are aluminum and other parts are stainless steel. Kits contain all necessary parts for conversion including hardware, cartridges and gaskets.

Go-No-Go®
Absorptive Cartridges
GNG Series

Double-Duty for Twice the Protection

Facet's Go-No-Go (GNG) absorptive cartridges perform two jobs with one cartridge. It absorbs water and removes solids reliably and efficiently. As the product stream flows from the outside of the cartridge to the inside, the GNG special water absorbent medium retains water, and the pleats expand. As the maximum water holding capacity is reached, there is a reduction in flow. The cartridge slows, then stops the flow of product as it reaches maximum capacity. This indicates that the cartridge is ready to be changed, assuring you of clean, dry product.

Benefits

- Absorbs highly emulsified water to less than 5 ppm
- Provides positive shut-off — increased differential pressure signals cartridge change-out

- Holds larger amounts of water than competition
- Ultra fine particulate removal efficiencies
- High collapse rating of cartridges
- Quick, easy cartridge change-out
- Easy housing installation

Standard Design Features

- Recommended max. operating temperature: 180 °F (82 °C)
- Maximum differential pressure: 100 psi (6.9 bar)
- Flow direction: Outside to in
- Layered multi-media pleated sections

Materials

- All metal components treated to protect against corrosion
- Special water absorbing medium
- Metal support shells
- Standard gasket material is Buna-N—other materials available upon request

Applications

- Fuel dispensing pumps
- Off-road machinery
- Service stations
- Marinas
- Truck stops
- Bus fueling
- Diesel fuel
- Gasoline
- Kerosene
- Other engine fuels
- Various oils

Absorptive Cartridges

FIWA Series

Double-Duty for Twice the Protection

Facet's FIWA absorptive cartridges perform two jobs with one cartridge. It absorbs water and removes solids reliably and efficiently from a wide range of petroleum products. As the product stream flows from the outside of the cartridge to the inside, the FIWA special water absorbent medium retains water, and the pleats expand.

As the maximum water holding capacity is reached, there is a reduction in flow. The cartridge slows, then stops the flow of product as it reaches maximum capacity. This indicates that the cartridge is ready to be changed, assuring you of clean, dry product.

Benefits

- Absorbs highly emulsified water to less than 5 ppm
- Provides positive shut-off —increased differential pressure signals cartridge change-out
- Holds larger amounts of water than competition
- Ultra fine particulate removal efficiencies
- High collapse rating of cartridges
- Quick, easy cartridge change-out
- Easy housing installation

Applications

- Fuel dispensing pumps
- Off-road machinery
- Service stations
- Marinas
- Truck stops
- Bus fueling
- Diesel fuel
- Gasoline
- Kerosene
- Other engine fuels
- Various oils

Standard Design Features

- Recommended max. operating temperature: 225 °F (107 °C)
- Maximum differential pressure: 100 psi (6.9 bar)
- Flow direction: Outside to in
- Layered multi-media pleated sections

Materials

- All metal components treated to protect against corrosion
- Special water absorbing medium
- Metal support shells
- Standard gasket material is Buna-N —other materials available upon request

Carbon Treater Cartridges

Materials

Bag Cartridge

- Polypropylene center tube
- Felt center tube migration barrier
- Tightly woven canvas or polyester bag
- Vibra-packed with 8 x 30 carbon
- Heavy-duty canvas hoisting handles

Canister Cartridge

- Polypropylene center tube
- Felt center tube migration barrier
- Non-woven polyester inner wraps
- Vibra-packed with 8 x 30 carbon to capacity
- Heavy-duty metal hoisting handle
- Engineered plastic end caps
- Polyester outer wrap
- Buna-N gaskets on both ends for assured sealing

The primary purposes of carbon treatment are:

- To remove chlorine, chlorinated organic compounds, odors, and unwanted colors
- The deoiling of industrial water
- The deodorization and decolorization of hydrocarbon based solvents

Facet's specially selected carbon has a large surface area and porous structure. It also has a high rate adsorptive capacity for the effective removal of solutes.

Standard Design Features

- Maximum adsorptive and filtration area
- Vibra-packed carbon minimizes settling
- Hoisting handles expedite cartridge installation and changeout

Applications

Absorption of:

- Hydrocarbons
- Organics
- Color
- Taste
- Chlorine
- Halogenated organics from potable, process, and plant effluent water

MODEL NUMBER	TYPE	DIRECTION OF FLOW	RECOMMENDED FLOW RATE PER CARTRIDGE		MEDIA	DIMENSIONS						MAXIMUM OPERATING TEMPERATURE	
			gpm*	lpm*		NOMINAL LENGTH		OD		ID		°F	°C
						in	mm	in	mm	in	mm		
CA-718	Canister	Outside/In	1-5	4-19	Carbon 8 x 30 Mesh	18	460	7	177	2 ¼	57	240	115
C-728-2	Polyester Bag	Outside/In	1-5	4-19		19	480	7	177	2 ¼	57	140	60
C-728-3	Cotton Bag	Outside/In	1-5	4-19		19	480	7	177	2 ¼	57	140	60

* Flow rates may vary as indicated, but the lower value offers the maximum adsorbency and the most efficient purification for each gallon processed.

Clay Treater Cartridges

The primary purposes of clay treatment are:

- To remove acids or products of oxidation from lube and hydraulic oils
- To remove additives and surfactants from fuel

Facet's specially selected Attapulugus clay greatly resists water saturation and provides maximum surfactant adsorptivity and filtration area found in clay treater cartridges.

Standard Design Features

- Maximum adsorptive and filtration area
- Greatly resists water saturation
- Vibra-packed clay minimizes settling
- Interchangeable with other manufacturer's bag and canister clay treater cartridges
- Hoisting handles expedite cartridge installation and changeout

Materials

Bag Cartridge

- Polypropylene center tube
- Felt center tube migration barrier
- Tightly woven canvas bag
- Vibra-packed with Attapulugus clay to capacity
- Heavy-duty canvas hoisting handles

Canister Cartridge

- Polypropylene center tube
- Felt center tube migration barrier
- Non-woven polyester inner wraps
- Vibra-packed with Attapulugus clay to capacity
- Heavy-duty metal hoisting handle
- Engineered plastic end caps
- Polyester outer wrap
- Buna-N gaskets on both ends for assured sealing

Applications

Facet's clay treater cartridges may be used to remove soluble contaminants such as acids, waxes, gums, resins, asphaltanes, sludges, carbon residues and colloidal particles from lubricating, hydraulic, seal, quench, and insulating oils (in circuit breaker, transformers). They may also be used for surfactant removal from jet fuel, gasoline, kerosene and diesel. They are often used to remove color from fuel to help bring back its normal appearance.

Carbon / Clay Treater Cartridges

Mounting Arrangements

Carbon and Clay Treater Housings

F Series

Standard Housing Design

- Welded carbon steel construction
- ASME Code, Section VIII construction, stamped and certified
- Design pressure: 150 psi @ 250 °F (10.3 bar @ 121 °C)
- Inlet and outlet permanently marked
- Interior: Epoxy coated
- Exterior: Prime coated
- Removable cartridge mounting post
- Swing bolt closure
- Buna-N closure gasket
- Hydraulic headlift

NPT Connections

- 1/4" differential pressure gauge
- 3/4" pressure relief valve and vent
- 2" main drain
- 1 1/2" side drain

Options

- Automatic air eliminator
- Differential pressure gauge
- Pressure relief valve
- Sampling probe
- Cartridge hoist assembly
- Removable bundle design

All dimensions are approximate and should be used for estimating purposes only.

NOTES:

- Housing model number will include cartridge model number when selected.
- Clay treater housings use Facet bag or canister style cartridges, 3 deep per stack.
- Clay cartridges are not installed at factory prior to shipment.
- Removable bundle design available on request. Contact your Facet Representative for details.

Air/Gas Filtration and Separation General Description

Definition

Air/gas filtration may be defined as the art of removing solid particulate matter from dry air/gas streams to free the stream of dust and other abrasive solid particulate matter. Air/gas filtration and separation may be defined as the art of removing solid particulate matter and liquids in suspension in air/gas streams. The field of air/gas filtration and separation filtration is one of a combination of removing either solids, or solids and liquids such as water and hydrocarbons, which may appear as slugs or in the form of mist or fog.

The above may be considered entrainment separation and while water or hydrocarbons may appear in an air or gas stream in a vapor form, the term entrainment separation would not apply to the removal of such contaminants in a vapor form. This removal would be properly classified under the category of dehydration which is sometimes referred to as purification. Entrainment removal will not lower the dew point of a gas stream; this can be accomplished only by vapor removal.

How Air/Gas Equipment Functions

The filtration of air/gas products is accomplished by passing the air or gas through a suitable filter media which permits the passage of the air or gas but retains the solids. This is a pure function of filtration identical to that of filtration of liquids, and is generally used only in cases of dry air or gas streams. However, solids may be removed in the presence of liquid entrainment, but the specific term "filtration" should not imply the liquids will be removed.

The filtration of air or gas may be further expanded by the use of an impingement baffle in the housing which would cause the knockout of coarse solids and entrained water or hydrocarbon. After the baffle, the air or gas then flows through a filter media which removes the finer solids; however, any remaining water or hydrocarbon after the baffle would pass through such a media.

Air/ gas entrainment filtration separation is accomplished by passing the product through a suitable first-stage baffle, then through the second stage coalescer cartridge which coalesces the water and hydrocarbons and removes the solids prior to entering the third stage. The third stage is a cartridge very similar to that of a filter cartridge except that special treatment makes it a water and hydrocarbon repellent member and causes the cartridge to repel discrete droplets of both water and hydrocarbons. It is

important that a large quiescent area be provided in the sump for the entrainment separator to function properly.

This permits the impinged droplets to fall out before they might be carried into the stream.

In cases of large gross amounts of solids, it is advisable to install a prefilter section in the housing to remove the gross solids, thus permitting the second-stage coalescer cartridge to remove only the finer solids and coalesce the water and hydrocarbons.

General Applications

- Removing solids and water which may damage gas-measuring equipment.
- Protecting dry bed desiccant towers from free water, oil distillate, etc.
- Removal of liquids and solids from fuel gas lines. Cleaning and conditioning charge stock in synthesis plants. (Example: Anhydrous ammonia synthesis using natural gas as a charge stock).
- Removal of free liquids and solids at inlet to compressor stations and between compressor stations. On compressor discharge to remove lubricating oil.

Selection of Equipment

The selection and size of equipment required to remove solids, water or hydrocarbon mist or fog from air or gas streams will depend on the flow rate, operating conditions, and physical characteristics of the gas. It is necessary to remember that any effective equipment must be designed to remove the desired amount of solids and other contaminants in one pass at full flow.

The amounts and types of solid and liquid contamination to be removed will have a bearing on the type of equipment and type of media selected. The location of the equipment also becomes a factor since proper operation of equipment frequently demands regular attention.

A basic fundamental in the selection of this type of equipment is the manufacturer's history of ability to upgrade media that will be interchangeable with the original media. In other words, is it possible to use cartridges with recently developed media that are dimensionally interchangeable with the cartridges originally purchased with the equipment? If so, no housing modifications are necessary to take advantage of advances in the state of the art. Facet standard cartridge dimensions permit such upgrading.

Air/Gas Filtration and Separation

General Description

Cost of Operation

Cost of operation of air/gas filtration and separation equipment is based primarily on operating costs.

Original equipment costs should be secondary. Filtration and separation equipment has a long life so reasonable differences in acquisition costs, apportioned over a long life, become minor factors in cost.

The true cost of operation is based on the cost per pound of solids or cost per gallon of liquids removed from the air or gas. Thus five factors make up the cost of operation:

1. Cost of media (cartridges, etc.)
2. Cost of service parts (gaskets, etc.)
3. Cost of maintenance labor
4. Cost of downtime to service or maintain (value of lost production)
5. Horsepower requirements versus ΔP

By accumulating the total of these five factors, a cost per unit may be arrived at on several bases, such as pounds of solids or gallons of liquid removed per million cubic feet of gas (month, year, etc.)

Design Criteria

Complete data is the prerequisite of any good design criteria. Therefore, all flow conditions, amounts of contamination, solids or liquids, operating pressure, operating temperature, and desired efficiencies all become an integral part of the data necessary for the adequate sizing and design of the proper equipment.

In designing a filter or an entrainment filter separator for air or gas, consideration must be given to the types of solids to be retained. As an example, consider the density of the solid with regard to the number of cartridges needed to hold a given volume of solids. It requires fewer cartridges to retain a given weight of a dense solid than is required to retain the same weight of a solid of lesser density. Also, particle size distribution affects the design by aiding in determining the volume of solids the specific cartridge can be expected to retain.

Capabilities

More than 75 years of experience in the process industry and in the removal of solids and water from aviation fuels has led to Facet's development of the media and housing designs needed to cope with the increasing demands for filtration and liquid removal from air and gas streams.

Facet's pipeline and out-of-storage experience can be used to a great advantage in gas transmission and out-of-cavern operations in the gas industry.

This, coupled with our experience in all types of filter applications, also provides the basis for handling in-plant applications of processing plant air for use on compressors and all types of air operations.

Air/Gas Coalescer and Separator Cartridges

AGB Series

Facet air/gas coalescer and separator cartridges remove solids and liquids from air or gas streams. Their most common uses are in air gas process streams, plant and instrument air streams, plant gas receiving points, gasoline processing plants, and refrigeration systems.

All cartridges are manufactured to rigid quality standards to ensure the media are held firmly against the center tube and securely adhered to the end caps in order to prevent pleat separation, bridging and/or deformation of media.

Coalescer Cartridges

Coalescer cartridges perform the dual function of coalescing liquids and filtering microscopic solids. Their construction is of interpleated resin impregnated cellulose and glass fiber media which combine excellent coalescing action with structural strength. The droplet sizing outer sock on the cartridges does not support fungus growth. The media are encased in a rugged perforated outer shell to permit an inside to outside flow direction.

Separator Cartridges

Separator cartridges perform the function of repelling discrete droplets of coalesced liquids which gravity does not force to settle in the sump. Their construction is of specially treated pleated resin impregnated cellulose. The treatment is applied in the cellulose manufacturing process under specifications supplied by Facet. Separator cartridges have an outside to inside flow direction.

Standard Design Features

- Recommended maximum operating temperature:
275 °F (135 °C) short exposure
240 °F (115 °C) continuous operation
- Maximum differential pressure: 40 psid to 75 psid (2.75 bar to 5.17 bar)
- Flow direction (coalescer): Inside to out
- Flow direction (separator): Outside to in
- pH range from 5 to 9

Materials

- All metal components are carbon steel with supplementary special treatment for positive corrosion protection
- Gaskets are Buna-N —other materials available on request

Air/Gas Vertical Housings

3AGB Series

The Facet 3 AGB Series vertical housing permits easy access for inspection or change out of media. The baffle plates at the inlet remove a large amount of solid particulate matter and entrained liquids which are collected in the quiescent sump. The large sump area also provides for slug control.

Use of the impingement baffle permits coalescer cartridges to function more efficiently in the removal of microscopic solids and the fine liquid entrainment.

Operation

Gas stream enter housing at point (A). Through the use of baffling at point (B), impingement of solid particulate matter occurs. A certain amount of liquid entrainment will drop out with solids and collect in quiescent sump. Mist and minute solids will flow upwards and enter coalescer cartridges, points (C). Oil mist particles will be coalesced and solid particulate matter will be removed. Gas stream will flow from inside-out. Coalesced droplets will be repelled by specially treated separator cartridges, point (D). Liquid will fall to bottom. An upper drain connection is available for this liquid to be removed at point (H). Gas stream will flow through separator cartridges (D) outside-in, and on through internal piping to outlet point (E).

Standard Housing Design

- Body: Welded carbon steel construction
- ASME Code, Section VIII, Div. 1, stamped and certified
- Designed for 150 psi @ 250 °F (10.3 bar @ 121 °C)
- Exterior: Prime coated
- Swing bolt head closures
- Head-Gasket: Buna-N o-ring —other materials available by request
- Headlift furnished on 20" (508 mm) OD and larger

Standard Connections

- Inlet and outlet: 150#RF (ANSI) flanged
- All other connections are 3000# NPT couplings

Options

- Differential pressure gauge
- Automatic drain valves
- Liquid level gauge

21 Series & 22 Series Housings

The Facet VF-21SB/22SB series housings, are economical, compact housings for superior in-line filtration protection when used with standard 21 Series or 22 Series cartridges.

Depending on the 21 Series or 22 Series cartridge installed, these housings may be used as filters, absorptive filters, filter separators or air/gas entrainment separators to remove solids, water mist or hydrocarbon carryover.

Both interior and exterior surfaces of the carbon steel body are epoxy coated to protect against corrosion. This sturdy, single cartridge housing is easy to maintain and requires only 2" (51 mm) base clearance for cartridge change out.

Standard Housing Design

- Carbon steel body
- Aluminum head
- Epoxy coated internally and externally
- 150 psi (10.3 bar) design pressure
- Swing bolt quick open closure
- Buna-N o-ring closure gasket
- Vent and drain connections w/ brass petcocks provided
- 1½" NPT inlet and outlet connections

VESSEL OPTIONS

Differential Pressure Gauge- The piston-type differential pressure gauge provides a simple visual warning. When 15 psi (1.03 bar) differential pressure is reached, the gauge indicator moves from green to red zone. This warning will prevent premature cartridge change-out.

Water Sight Glass- The water sight glass provides an easy means to detect water in the sump. The weighted ball, visible in the sight glass, will float only when water is present. The floating ball is an indication water should be drained from the housing to prevent both cartridge contamination and water traveling downstream from the housing.

ACCORDING TO THE REQUIREMENTS OF EUROPEAN PRESSURE EQUIPMENT DIRECTIVE (PED) 2014/68/EU ART. 4.3, WITHIN THE OPERATING LIMITS PROVIDED ON VESSEL NAMEPLATE AND SUMMARIZED BELOW, THESE FILTERS ARE DESIGNED AND MANUFACTURED IN ACCORDANCE WITH THE SOUND ENGINEERING PRACTICE AND EXEMPT FROM CE MARKING AND CERTIFICATION: 10 BAR(G) @ 35°C FOR AV-GAS AND JET FUEL.

21 Series Cartridges

Standard Design Features

- Recommended maximum operating temperature: 180 °F (82 °C)
- Maximum differential pressure: 75 psi (5.17 bar)
- pH range from 5 to 9
- Flow direction: Outside to in
- Cartridge dimensions: OD - 6" (152 mm), ID - 1 1/2" (38 mm), Nominal Length - 9" (229 mm)

Materials

- Carbon steel structural components
- All metal components coated to protect against corrosion
- Standard gaskets are Buna-N —other materials available on request

Facet SuperFlex housings are small, economical, carbon steel housings that may be used as filters, filter separators or air/gas separators depending on the cartridges used. Stainless steel construction is available. Contact your Facet Representative for details.

Liquid Filtration

MS Series SuperFlex Filters remove solids from liquids, compressed air or natural gas. Facet's M Series (high efficiency, screen wrapped or multipleated) cartridges, stacked 1, 2 or 3 high, are used.

Liquid-Liquid Separation

VCS Series SuperFlex Filter Separators remove water and solids from gasoline, diesel fuel, fuel oil, insulating oil, kerosene, lube oils, solvents and many other petroleum based products where water content is a problem. This housing requires Facet Model CC-23-7 or CC-23C coalescer cartridges and Model CS-94 or CS-94C pleated paper separator cartridges, stacked 1, 2 or 3 high.

Air/Gas Separation

AGS Series SuperFlex Air/Gas Separators remove oil, water, mist and solids from compressed air or natural gas. This housing requires Facet Model CC-23-7 coalescer cartridge and Model CS- 98-2 pleated paper separator cartridge.

Standard Housing Design Features

- Welded carbon steel construction
- ASME Code, Section VIII, Div. 1, stamped and certified
- Designed for 250 psi @ 250 °F (17.23 bar @ 121 °C)
- Main closure: Blind flange
- Head gasket: Buna-N o-ring —other materials available on request
- Vent connections: 3/4" NPT
- Drain connections: 3/4" 3000# NPT
- Inlet and outlet connections: 2" 3000# NPT
- Interior: Epoxy coated
- Exterior: Shop primer

Options

- 304 stainless steel construction
- Air eliminator
- Drain valve
- Pressure gauge assembly
- Pressure relief valve
- Adjustable support stand

Screw Base Adapter

Top view

Side view with bolt

Bottom view

Side view

Improved design for added strength

Facet's screw base adapter has been redesigned to provide the strongest adapter on the market today. The adapter is now made of aluminum with increased locating pin strength when compared with other designs. Gasket material is Buna-N.

The adapter may be used with all Facet 6" (152 mm) diameter screw base cartridges and is compatible with cartridges from other manufacturers.

The design is compatible with all aviation fuels and provides a temperature range up to 250° F (115° C). It is also interchangeable with Velcon's 6000T screw base adapter.

PART NUMBER	COMMENTS
677453A-AM*	1/2" bolt for Facet Vessels
677453A-375-AM*	3/8" bolt for Velcon Vessels

CENTER ROD	
Overall Cartridge Length (in)	Part Number
14½	678901
28¾	678905
43¼	678907
57¼	678909

Note: Nuts, washers and center rods are stainless steel.

Yoke Bypass Valve

The Facet yoke bypass valve was developed to allow continuous flow in applications where it is critical not to stop the process.

Rather than expensive instrumentation and valves used to automatically bypass the vessel, this yoke bypass valve will open at a set pressure allowing product to bypass the elements.

The yoke bypass valve can be set to open at differential pressure from 5 psi to 45 psi.

When ordering, specify part number 695931 and set pressure.

Cleaning Procedures - Teflon® Screen and Synthetic Separator Cartridges

It is recommended that this procedure is carried out with every coalescer change to ensure full potential and longer life of the separator. Make sure hands are kept clean and free of grease or other contamination throughout the cleansing operation. It is also recommended that gloves (preferably thin rubber) be worn throughout this operation so as to avoid contact between bare hands and the separator screen / mesh.

1. CAREFULLY remove each element from the filter separator.
2. Submerge the element in clean, dry fuel and wash it using a gentle, reciprocating action, holding the element first by one end cap and then the other. (DO NOT touch the separator screen/mesh with your bare hands, or allow any grease to come into contact with the element.)
3. Holding the element by the endcaps, visually inspect the entire surface of the screen for damage and contamination. If there are any visible flaws or debris that have not been removed by washing, the cartridge should be replaced.
4. While separator is fuel wet, hold the element horizontal and allow tap water to drip onto the screen. The water must not be sprayed and it must not fall more than 3" (7.5 cm) before contacting the screen. The water will run off instantly if the element is not contaminated. Continue testing the element by slowly rotating and moving it back and forth until the entire surface has been tested. If the water does not run off, but disappears through the screen and is found inside the element, then the element has to be further cleaned as described in step 6.
5. If the element passes the surface inspection (step 3) and the water test (step 4), rinse it thoroughly in clean fuel to remove traces of water and air dry prior to reinstalling.
6. If the element fails the water test (step 4), it may be further cleaned by repeating the cleaning stage (step 2) using isopropyl alcohol in place of fuel. After cleaning, the element should be drained and rinsed in clean, dry fuel to remove all traces of isopropyl alcohol if used. Another alternative is to use a spray of hot water (not from a pressure washer). Allow the cartridge to fully dry. After using either procedure, repeat the water test (step 4). If the element does not pass the water test after this operation, it must be replaced.
7. If there are visible tears, nicks, or cuts, they can be repaired as long as they are not larger than 1/8" in diameter. Use brightly colored fingernail polish or epoxy to repair the area. The nail polish allows repairs to be easily observed in the future. After you have repaired the element, wet the element in fuel and repeat the water test (step 4).

NOTE: The use of detergents (i.e., soap, powder cleanser of any kind), steam, or compressed air during any of the above operations IS NOT RECOMMENDED because they can affect the operation of the separator.

Frequently Asked Technical Questions

1. What is the operational life expectancy of the Teflon and Synthetic cartridge?

Facet Teflon & Synthetic separator cartridges are cleanable and reusable. They should be inspected and tested before reusing. Cartridge service life should not be extended beyond 5 years. Follow Facet cleaning procedures for Teflon and Synthetic cartridges.

2. What is the shelf life expectancy of the Facet cartridges?

Most elements are a minimum of five years if sealed and in temperature controlled environment. Monitor should be installed within 2 years of shipment from Facet stock.

3. When do I change out my coalescer separator?

- A. Coalescer elements must be replaced when:
1. Filter Membrane (Milipore®) Test indicates elements are not performing (Refer to Section 3).
 2. Corrected Differential pressure exceeds 15 psi or there is a sudden drop in differential pressure.
 3. Continuous sump samples indicate surfactants, microbial or solid contaminants.
 4. Free water detection test indicates elements are not performing (Ref. Section 3-3).

4. Is there a minimum flow rate coalescer separators?

Operating a coalescer separator at less than 25% of rated flow, along with extended periods of inactivity, can increase the risk for microbiological growth on the elements due to free water not being released from the coalescer.

5. What is the typical clean differential pressure drop?

Filter/separators	2-4 psid clean at ambient temp.
Micronic Filters	.5-4 psid clean at ambient temp.
2" Monitors	6-7 psid clean at ambient temp.
6" Monitors	3-4 psid clean at ambient temp.

6. Typical element change-out recommendations at maximum rated flow.

Filter/Separators	15 psid
Monitors	15 psid
Micronics	15 psid
"HP"	15 psid
Clays	Based on MSEP test

7. What is the rupture pressure for each element?

Filter/Separators	75 psid
Monitors	174 psid
Micronics	75 psid
"HP"	15 psid
Clays	N/A

8. What is the purpose of the Slug valve?

The slug valve stops the flow of product when excessive water is collected in the coalescer separator sump. It works in conjunction with the float control. The slug valve can also be furnished with rate of flow control which is used to control flow through the coalescer separator and with a check valve feature to prevent back-flow.

Frequently Asked Technical Questions

9. What is the operation of a Water Probe?

The water probe detects the level of water electronically and then can open and close the auto water drain valve or slug valve, shut down pump and send alarm to control panel.

10. What is the reason for a Clay Treater?

The clay treater removes surfactants from fuel to allow coalescer separators to perform properly. The surfactants will disarm the coalescer elements.

11. What is the function of the vessel heaters?

The heater keeps water from freezing in the sump and drain lines.

12. What data do you need to know to size a vessel?

Refer to Application Data Sheet in your catalog.

13. Which should be used, clay bags or canisters?

Canisters have gaskets that improve sealing and have less chance of bypassing. Bags, on the other hand, hold more clay and cost about 40% less.

14. Can clay bags be used in Velcon vessels?

Not usually. Velcon vessels are built similar to "M" series filter vessels except without adaptors for cartridge sealing. They use center rods, center seals, and end caps. There are conversion kits but are cost prohibitive. Two things to remember, this can be a tremendous selling tool for Facet vessels, but it does add additional cost.

15. What colors are used for what fuels?

Jet - Clear
AV Gas - Blue,
High Sulfur Diesel - Red.

16. Can dye (color) in fuels be removed?

In most instances, "no."

17. Why use horizontal versus vertical housing?

Space and ease of maintenance.

18. Should a filter be installed upstream of a coalescer separator?

Depends on the application. If the customer is having a problem with solids you should definitely have a micron filter in front of your coalescer separator. The micron filter is anywhere from a third to a fourth of the cost and has four times the surface area.

19. What is the difference between free and entrained and dissolved water?

1. Free water is created when the fuel has all the water it can dissolve plus more. This extra water is then free water. Free water is usually not visible as a haze until you get above 30 to 40 ppm free water. This free water is all that a coalescer or absorbent cartridge can remove.
2. Entrained water: Discrete water droplets carried by a continuous liquid or gas phase when water is immiscible with the liquid. May be separated from the continuous phase by coalescing and gravity separation. Usually picked up in a system by condensation or a water washing used in process.
3. Dissolved water is the water that is in solution or basically not visible in the fuel. The amount changes with temperature. Fuel holds more water as the temperature increases.

Frequently Asked Technical Questions

20. Is the delta P gauge on a clay treater actually telling you anything?

Not really. This is a common misconception. The only true way to tell if the clay is working is to take a MSEP test. This test will be taken on the inlet and the outlet and compared. The reading from the outlet should be higher. A good quality fuel has a reading of 85 or better. The closer you get to 100 the better the fuel quality. If the fuel going in is 80 and the outlet is 80 or less, you would need to change out the clay.

21. How many pounds of solids does our MP series filter element hold?

Up to 3-5 pounds per 14" length dependent upon the micron rating and type of solids present.

22. With AVGAS, can you flow more through the same coalescer separator?

The Energy Institute has extended Specification EI 1581 to include Av-Gas that is hydrocarbon based and has aromatics content that is similar to Jet Fuel under Category C sizing and flow.

23. What is the recommended sealing torque on screw base cartridges?

30 lbs. Ft.

24. What is the mesh size and micron rating of Facet's Synthetic separator?

50 micron, 267 mesh.

25. What are the benefits of Facet's CIF Cartridge?

No metal components, less expensive while maintaining high efficiency of M Series elements and reduced disposal volume and cost.

26. Does the size of the water droplets indicate the coalescing efficiency?

Downstream: Yes, the bigger the drops the more the fall. Saves Separator from having to do anything.

27. How is the gallon per minute of the coalescer calculated?

Flow per linear inch which is based on EI test (Jet Fuel).

28. Can our immersion heaters be wired for a signal light?

Yes.

29. What are certificates of similarity?

To provide certificate of test data in similar type vessels using flow rates that determine the correct amount of coalescers and separators. Upgrading an older vessel to EI 1581 current edition or changing from competitor vessel to Facet.

30. Are Material Safety Data Sheet (MSDS) required for the products manufactured by Facet?

Items manufactured by Facet are considered "articles" by definition of the regulations and therefore do not need MSDS sheets.

31. What is the correct procedure for draining the sump on a coalescer separator?

Per ATA-103 guidelines, drain fuel at maximum practical flow into a suitable container. The vessel must be pressurized, but fuel does not have to be flowing.
